

# Trees : Non Linear Data Structure in which items are arranged in sorted sequence. It is hierarchical ds which stores info naturally in the form of hierarchy style.

Top node is the root node.

node below root are child node

Leaf Nodes  $\rightarrow$  Nodes who has no child

Sub Tree  $\rightarrow$  Root de andre tree bne

internal node  $\rightarrow$  node de andre node

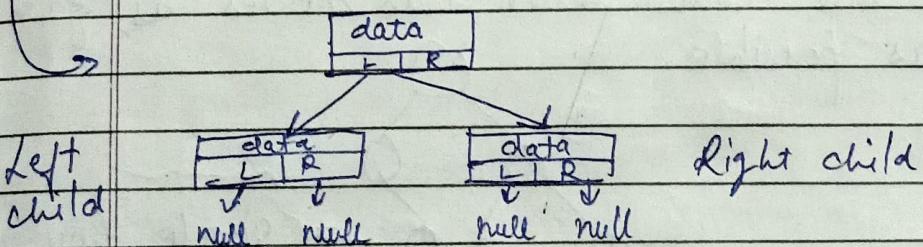

Degree of node  $\rightarrow$  eg If a node has 3 children then its degree is 3.

Degree of tree  $\rightarrow$  ~~max~~ max no. of any node.

Height of binary tree

\* Binary Tree  $\rightarrow$  almost 2 children i.e.  $(0, 1, 2)$

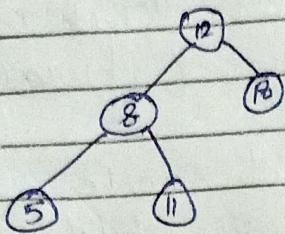

Bottom most node  $\rightarrow$  leaves.

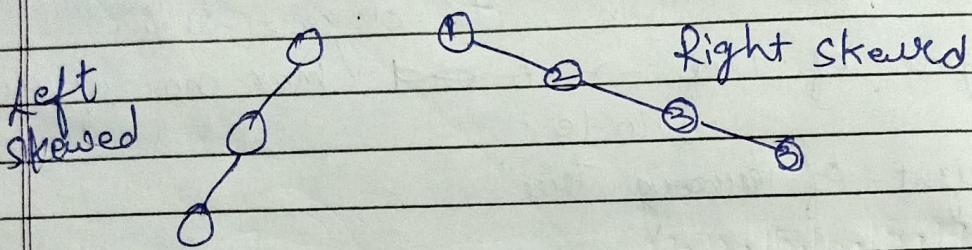

$\rightarrow$  Types of Binary Tree :

- Base on no. of children  $\rightarrow$  Full Binary Tree, Degenerate / Skewed.
- Base on Completion Level  $\rightarrow$  complete, Perfect, Balanced
- Base on node Value  $\rightarrow$  Binary Search, AVL, Red Black, B Tree

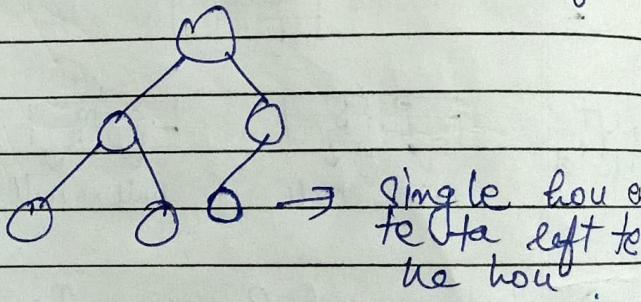

- Full Binary  $\rightarrow$  Every node has 0 or 2 children (no node has exactly 1 child)

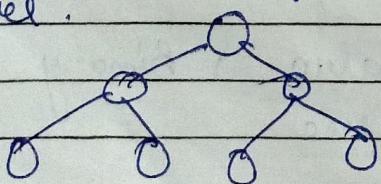

- Degenerate / Skewed: Each parent node has only 1 child. Form structure similar to linked list.

- Complete Binary Tree: All levels except possibly the last are fully filled. The last level has nodes as far left as possible

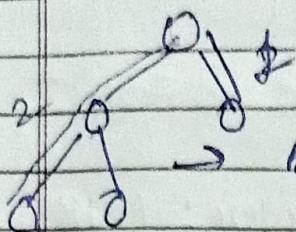

- Perfect: Internal nodes have exactly 2 children & all leaf nodes are at the same level.

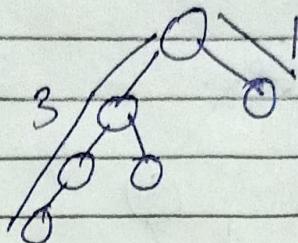

$\eta [-1, 0, 1] \rightarrow \text{Balance} \quad \boxed{\dots}$

- Balanced: height diff b/w the left & right subtrees of any is at most 1

$$|2 - 1| = 1$$

→ Balance

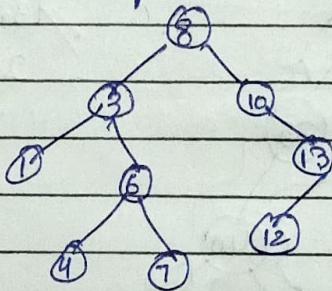

$$3 - 1 = 2$$

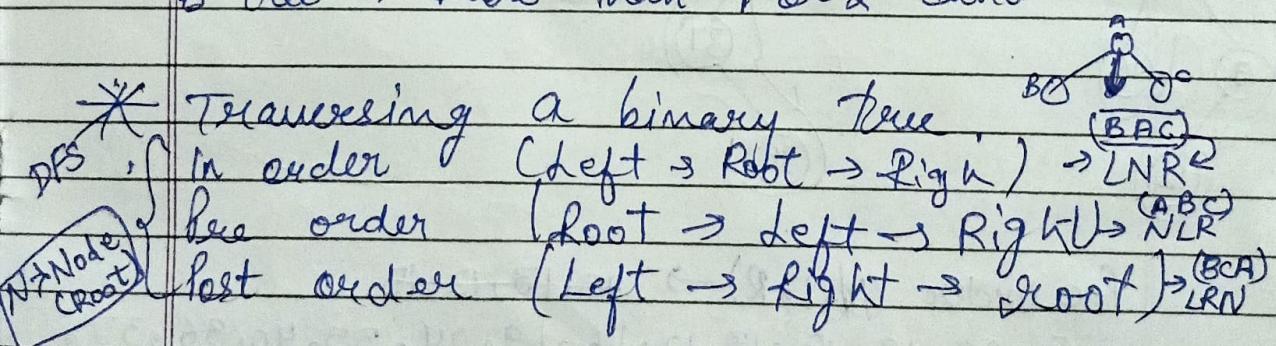

unbalance

Balance if height of tree is  $O(\log n)$   
where  $n$  is no. of nodes.

- Binary Search: left subtree contain smaller values than root & the right subtree contains greater values than the root

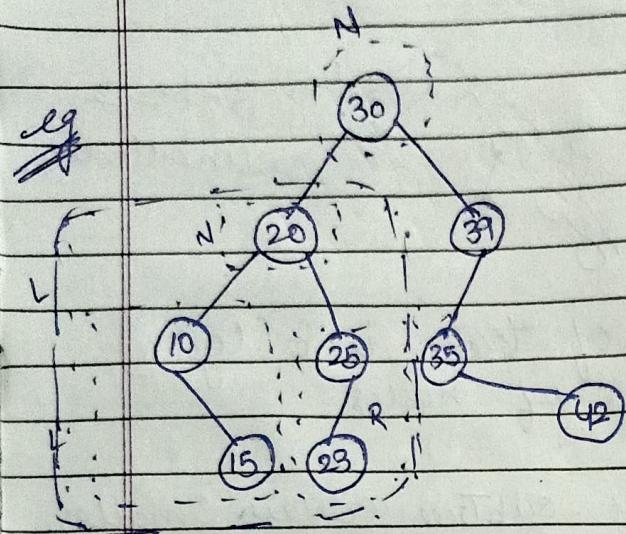

- B Tree → more than 1 or 2 child.

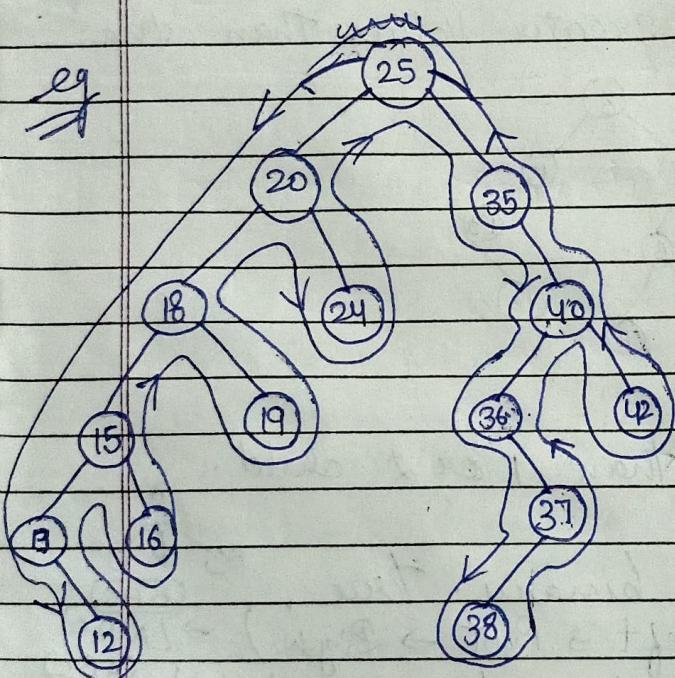

Tree - Traversal

- # DFS → In-order, Pre-order, Post-order traversal
- # BFS (Breadth First Search algo) →

## # Binary Search Tree :- (BST)

Properties :-

- 1 The elements that are on left side are smaller than root node
- 2 The elements that are on right side are greater than root node.

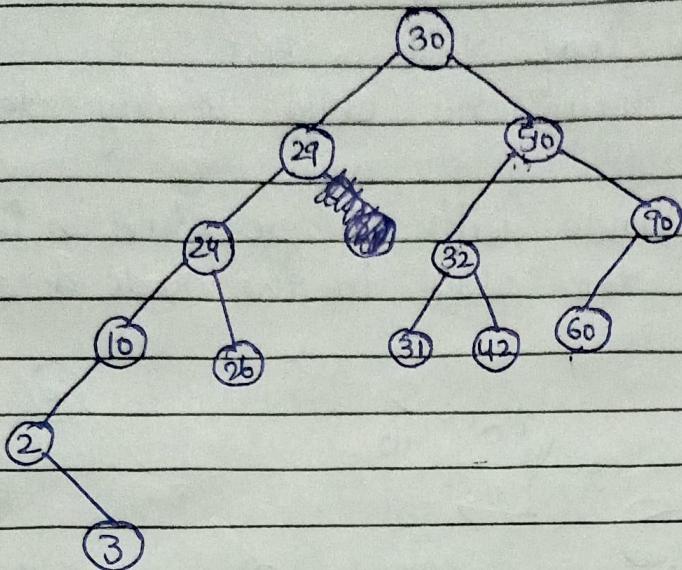

e.g. 5, 9, 3, 2, 8, 1

No. of nodes = height

O(h) is the complexity  $\rightarrow$  in searching

eg. 30, 50, 90, 60, 32, 29, 24, 26, 31, 42, 10, 2, 3

BST used to organize & store data in sorted manner

### Properties

- Hierarchical structure allow for efficient Searching, Insertions & Deletion.

### Properties

- The left & right subtree each must also be a BST
- There must be no duplicate node.

## # Insertion in BST

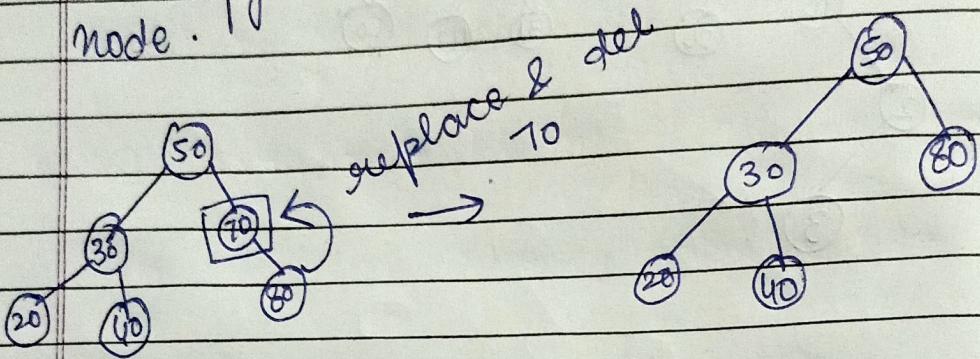

- Compare new element with root node
- If value is less than move to left else right.
- If the value is null then insert the new value

# ~~selection~~ searching is also same as insertion  
this we point the element when we find it.

## # Deletion

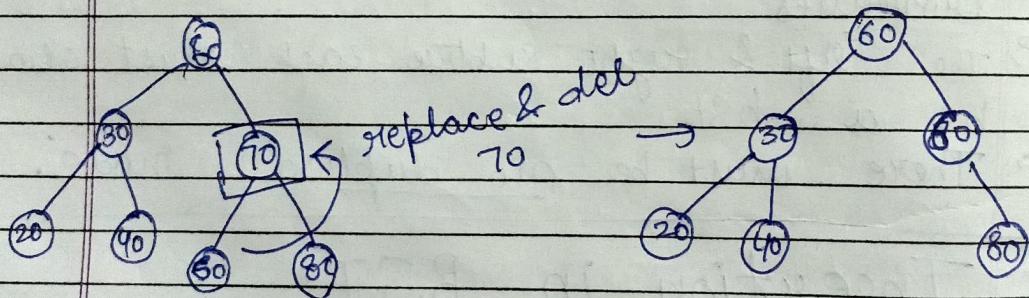

Case 1: Delete a leaf Node in BST  
When there no child simply del it.

Case 2: Delete a node with single child in BST  
Copy the child to the node & delete the node.

Case 3: Two Children.

- Find the in order Successor (small value in right sub tree).
- Replace the nodes value with in order Successor's value
- Delete the in order Successor node.

Time Complexity

- Best Case :  $O(\log n)$  for Balanced bst
- Worst Case:  $O(n)$  for skewed bst

## Space

- $O(\log n)$  for recursion in balanced BST
- $O(n)$  for recursion in skewed BST

## → Disadvantages of binary Search Tree:

1. Unbalanced Trees: If elements are inserted in a sorted or nearly sorted order, the BST can become unbalanced, resembling a linked list. This leads to degraded performance with operations taking  $O(n)$  time instead of average  $O(\log n)$  time.
2. Space Complexity: BSTs require additional space for pointers (left & right children) which can lead to increased memory usage compared to other data structures like arrays, especially for large datasets.
3. Complexity of Balancing: Maintaining a balanced tree can be complex & requires additional algorithms or data structures (e.g. AVL trees, Red-Black trees) to ensure that the tree remains balanced after insertions & deletions.
4. No Duplicate keys: Standard BSTs do not allow duplicate keys, which can be a limitation in applications where duplicate entries are necessary or useful.
5. Performance Variability: The performance of BST operations can vary significantly based on

the order of insertion & deletions making it less predictable compared to other ds.

6. Traversal Complexity: While in-order traversal of a BST can yield sorted order, other traversal methods (pre-order, post-order) can be less intuitive & may require additional logic for specific applications.

7. Implementation Complexity: It can be more complex than using simpler data structures, especially when considering edge cases like balancing, deletion of nodes & handling of various node configuration.

## AVL Trees

- Defn
- Invented by GM Adel'son-Velsky & EM Landis in 1962
  - A height-balanced bst where each node is associated with balance factor

$$\text{Balance Factor } (k) = \text{height}(\text{left}(k)) - \text{height}(\text{right}(k))$$

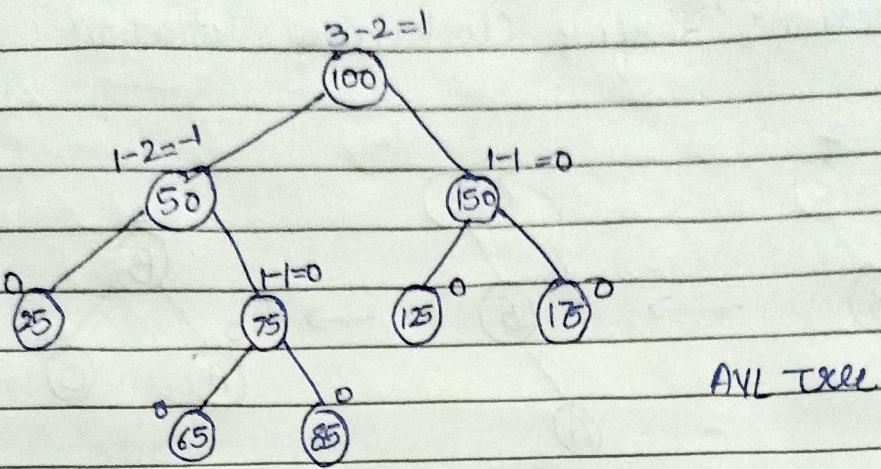

- Balanced if balance factor  $\in \{-1, 0, 1\}$ .

→ We use rotation in unbalanced tree to balance it.

### Properties

- If a balance factor of any node is +1 : Left subtree is one level higher

- 0 : Both subtrees have equal height.
- -1 : Right " is one level higher

→ why AVL tree?

- control the height of BST
- prevent BST from becoming skewed.

Time Complexity

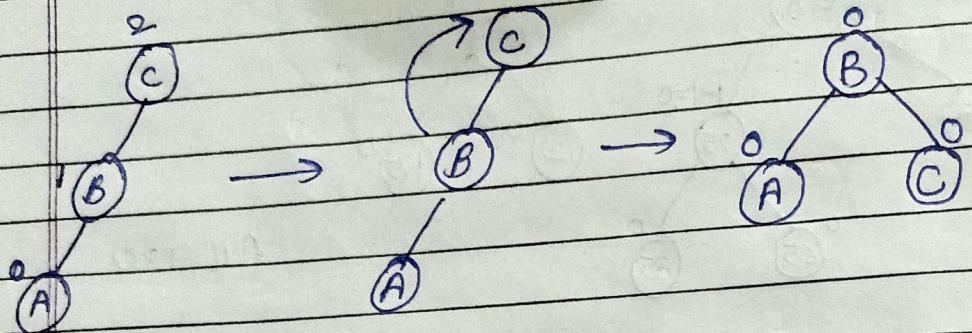

→ Op are  $O(\log n)$  in AVL tree vs  $O(n)$  in Skewed BST

| Op     | Aug Case    | Worst Case  | complexity of AVL tree of. |
|--------|-------------|-------------|----------------------------|
| Space  | $O(n)$      | $O(n)$      |                            |
| Search | $O(\log n)$ | $O(\log n)$ |                            |
| Insert | $O(\log n)$ | $O(\log n)$ |                            |
| Delete | $O(\log n)$ | $O(\log n)$ |                            |

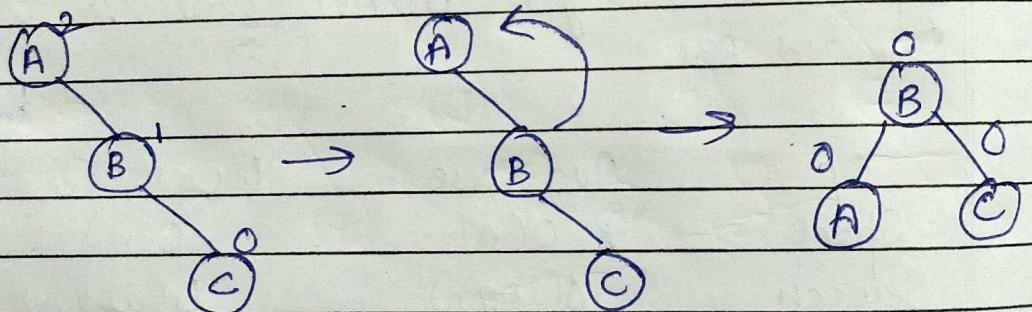

→ Types of rotation

- LL (Left-Left) : Single rotation for left skewed subtree
- RR (Right-Right) : " " " right " "
- LR (Left-Right) : Double " ; RR on subtree, then LL on root
- RL (Right-Left) : " " " ; LL " " " -> RR " "

- LL Rotation
- case: Node inserted into the left subtree of the left subtree.
  - Action: Perform clockwise rotation.

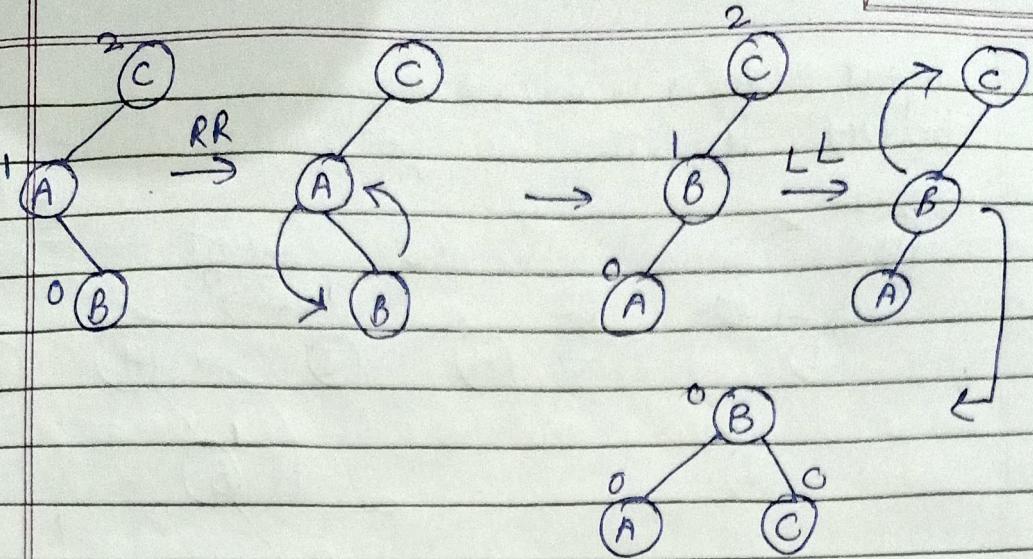

- RR Rotation
- case: Node inserted into the right subtree of the right subtree.
- Action: Perform anticlock wise.

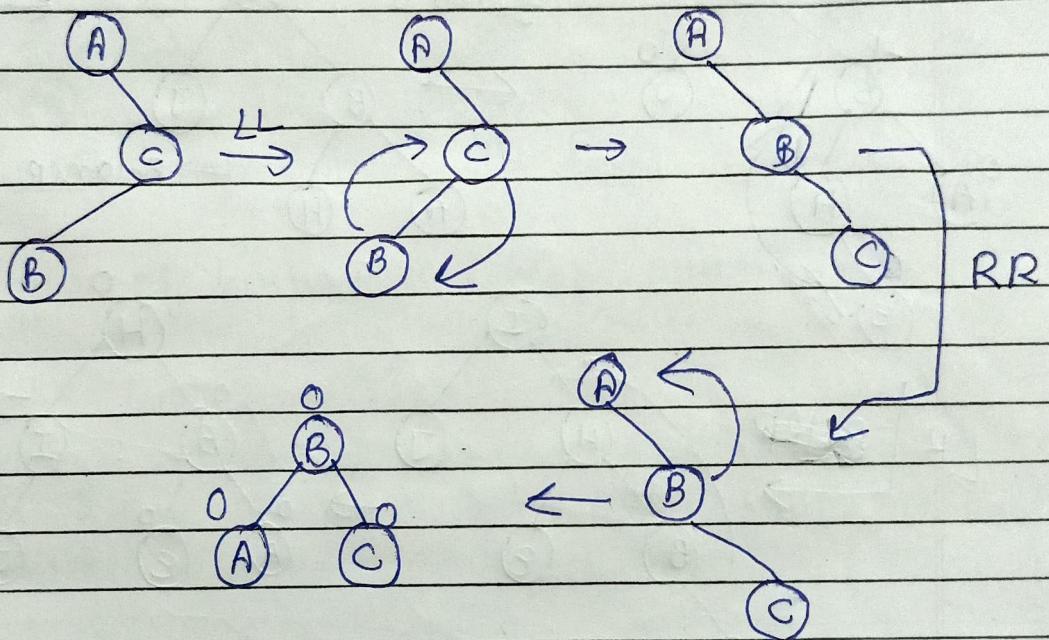

- LR Rotation
- case: Node inserted into the right subtree of the left subtree.
- Action: RR on Subtree, LL on root.

→ BR Rotation + LL Rotation, RR is performed on Subtree & then LL is performed on full tree.

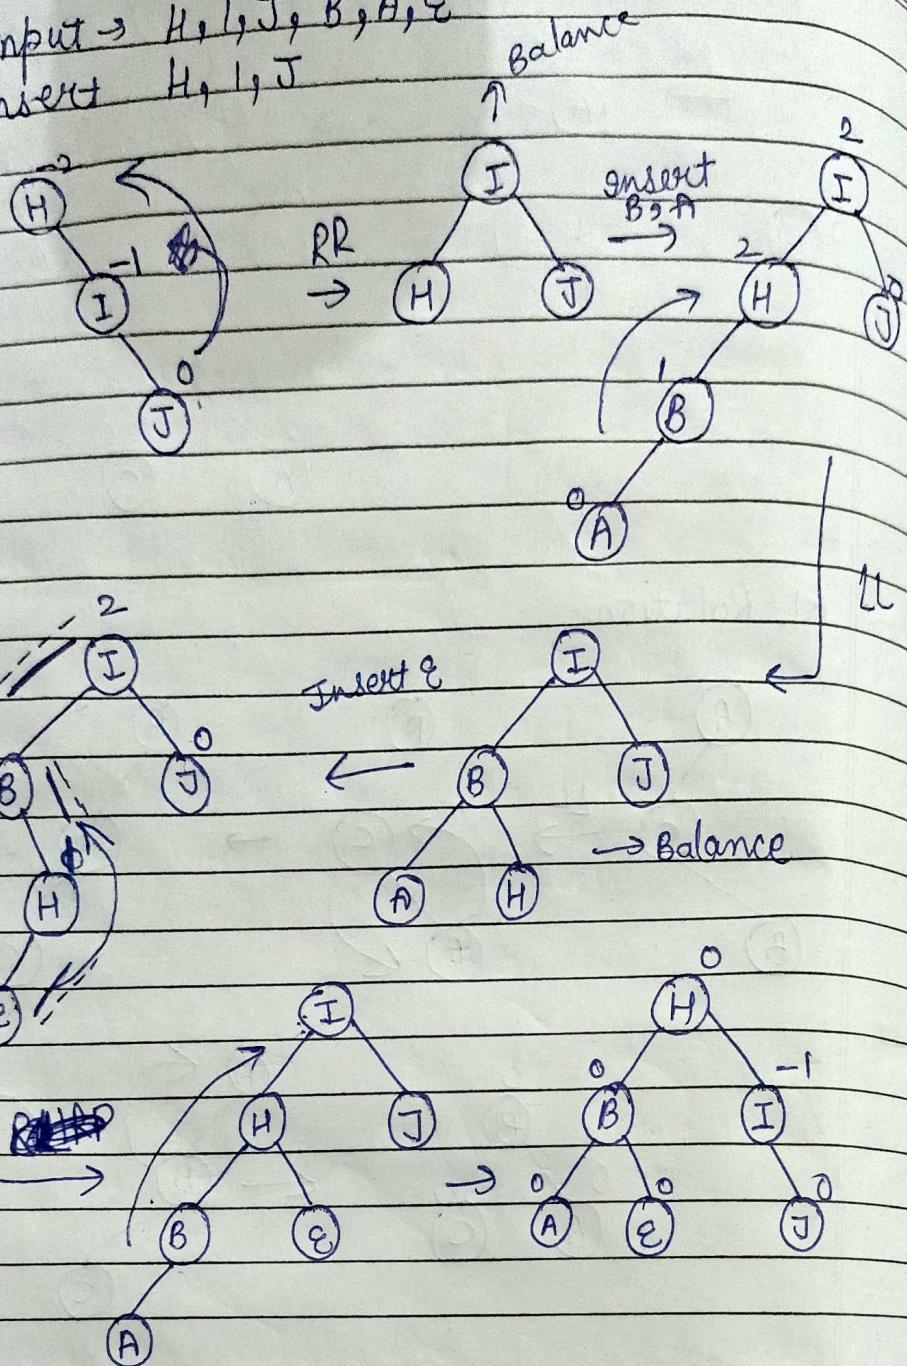

→ RL Rotation

Eg

Input  $\rightarrow H, I, J, B, A, E$   
Insert  $H, I, J$

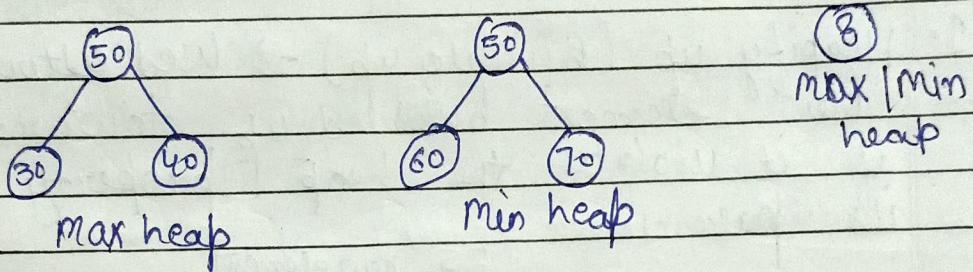

## # Application

- 1 Database Indexing.
- 2 Memory management
- 3 File System
- 4 Network Routing
- 5 Data compression
- 6 Gaming & Simulation
- 7 Compiler Design
8. Scheduling Systems

# Heap: It does not satisfy ~~binary search~~ property & never be a ~~bst~~.

- Type of binary tree.
- 2 Main rules / Properties:
  - Shape Property: complete binary tree
  - Heap Property:  
Max heap  $\rightarrow$  Parent node is greater than or equal to child node.  
Min heap: Parent node is less or equal to child node

Types of heap  $\rightarrow$  max heap, min heap.

- Why use a heap?
  - Manage a set of elements, help in sorting, efficient in insertion & deletion while maintaining order.

- Properties:
  - Min & max element is always at the root of the heap allowing constant-time access.
  - Parent index  $\leftarrow \frac{i}{2}$ , left child =  $2i+1$ , right =  $2i+2$

# Heap operation: Insert & delete elements.

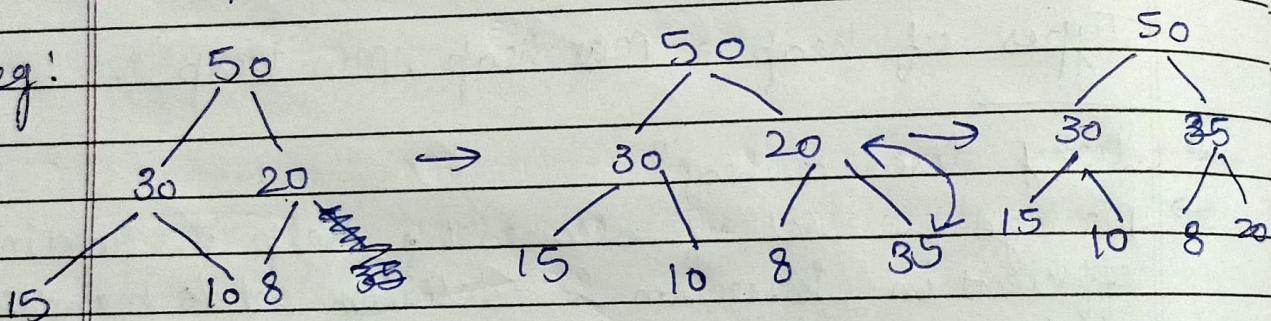

- Maintain heap property using ~~not~~ heapify
- rearranging the elements to maintain heap property
- when converting an arbitrary array in heap called building a heap

How heapify work.

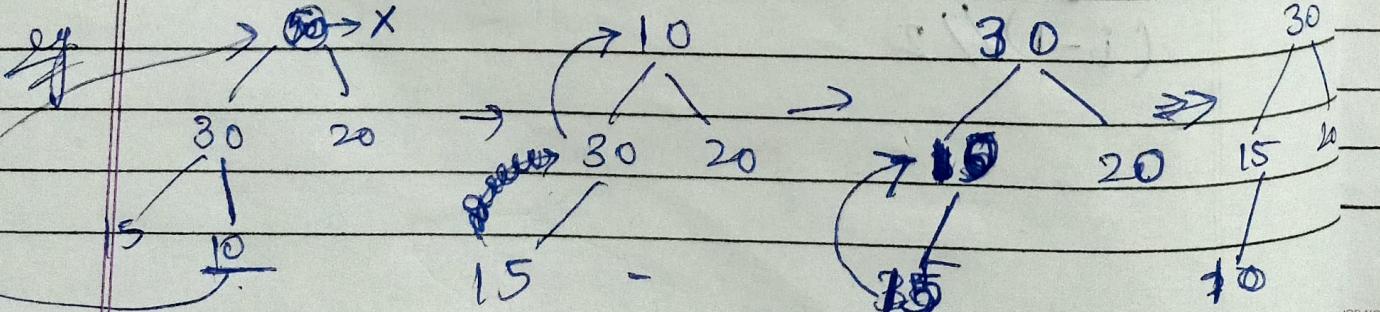

1. Heapify up (Bubble up) → Used after insertion
- New element bubbled up toward root if it violates the heap property with its parent.

35 new element

e.g:

2. Heapify down (bubble down) → Used after deletion / removing the root element or replacing it.
- If the rules violated then the element bubbled down.

## # Key characteristics

1  
2  
3  
4

- Not a binary tree
- Efficient operation: Find max/min  $\rightarrow O(1)$   
; Insert/del  $\rightarrow O(\log n)$  : tree is balanced due to shape property
- Storage in arrays: Heaps often implement in array : of complete binary tree structure

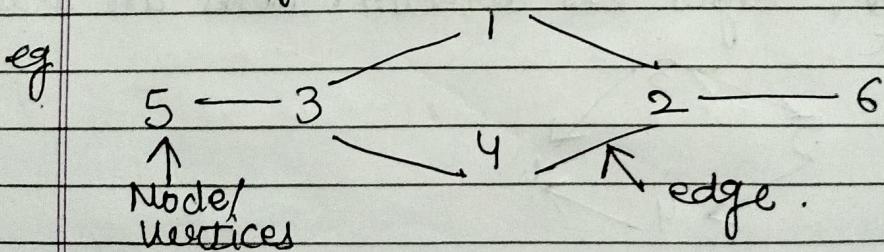

## # Application.

- Priority queue: efficient to retrieve high/low element
- Heap Sort: sort an array in  $O(n \log n)$  time
- Graph algo: used in Dijkstra & Prim's algo.
- Median Pinder: Dynamic data sets require heaps to maintain median efficiently

## # Graphs DS : Set of vertices & edges.

Q ~~Q~~ <sup>Q</sup> Diff b/w graphs & trees.

Graphs: Non linear ds consisting of vertices (nodes) & edges.  
denoted by  $G(V, E)$   $V = \text{vertices}$   $E = \text{edges}$ .

Real World Analogy: Football game: Player are nodes, interaction as ball pass ~~time~~ edges  
1k duje re

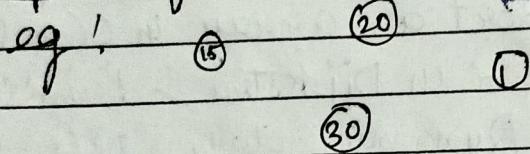

# # Components of graph

Date / /  
Page No. / /

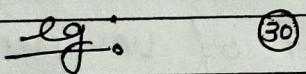

- Vertices (Nodes): Fundamental unit  
: can be labeled / unlabelled [No. or name]
- Edges (Connections): connect two nodes  
: can be directed or undirected,  
labeled or unlabeled.

## # Types

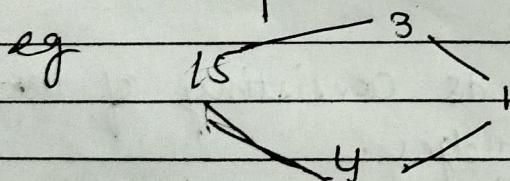

1 Null graph: If there is no edge at all.

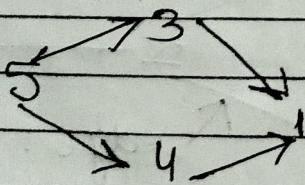

2 Trivial: Single vertex, smallest graph possible.

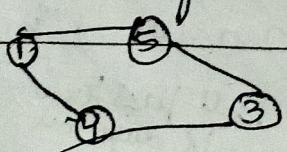

3 Undirected: No direction. Nodes are unordered pairs in the definition of every edge

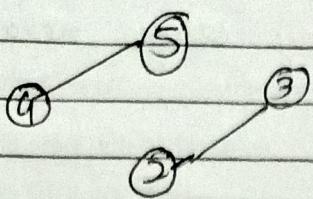

4 directed: Edges has direction. Nodes are ordered

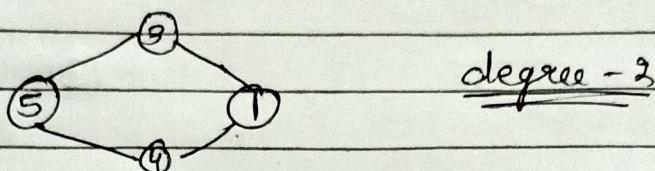

5 Connected: Every vertex is connected

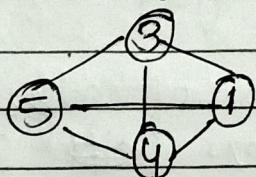

6 Disconnected : At least one edge is not connected or unreachable

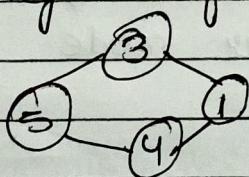

7 Regular : degree of every vertex is equal to  $k$ .

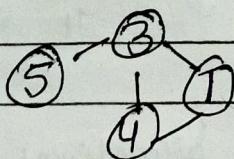

8 Complete : each & every vertex is connected with other vertex.

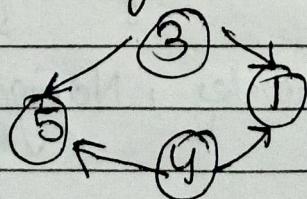

9 Cycle : Min degree of each vertex is 2

10 Cyclic : Contain at least one cycle

• Directed Acyclic: No cycles in a directed graph

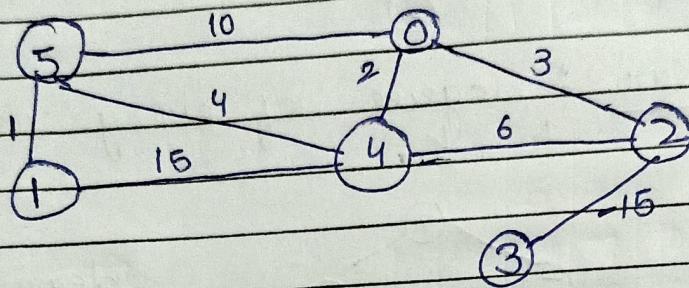

#

# Weighted Graphs :

|          |     |
|----------|-----|
| Date     | / / |
| Page No. |     |

- Defined as a special type of graph in which the edges are assigned some weight which represent cost, distance & many other relative measuring units.

Subtypes :

- Directed Weighted graph
- Undirected Weighted graph

# Degree (Vertex) : no. of edges incident to the vertex. ~~(if)~~ <sup>directed</sup> If outgoing well  
we count how

OR No. of relations a particular node make with other node

Type of Degree .

- In degree : no. of edges coming to vertex
- Out degree : " " " " out from vertex

Adv. Models real-world problems effectively.

Efficient for many algo. (e.g. Shortest Path)

Application • Social Networks, Navigation, Sport analysis etc

# # Representation of Graphs!

Date: / /  
Page No. \_\_\_\_\_

Matrix

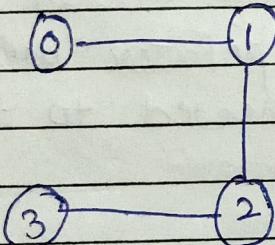

- Most Common representation:
- adjacency ~~matrix~~
  - adjacency list

- Adjacency Matrix: graph is stored in the form of 2D matrix where rows & columns denote vertices.
- Each entry in the matrix represents w<sub>i,j</sub> of edge b/w those vertices.

Connect hega ta 1 nhi ta 0.

# Delete: Firstly remove the connection, then pop the element.

## # Graph Traversal ↴

- Process of visiting all the vertices (nodes) on edges of a graph in a systematic manner.
- It ensures that every vertex is reached at least once.

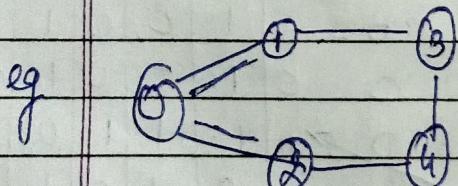

### Types of Traversal

I. BFS (Breadth first search): Traverses level by level, exploring all neighbors of node before moving to next level.  
Also known as Level order traversal

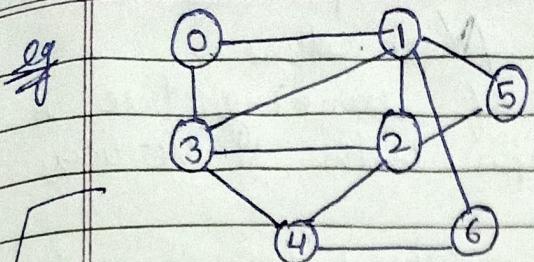

→ Uses a Queue (FIFO Structure)

→ Can consider any node as the root node.

Process: Start with Root Node → Dequeue Node  
enqueue node ←

|          |   |     |     |     |   |
|----------|---|-----|-----|-----|---|

# Spanning Tree: It is a subgraph of a graph  $G_1$  that includes all the vertices of  $G_1$  & the minimum possible no. of edges such that there is no cycle.

→ graph can have multiple Spanning Tree.

- # Properties: • Exist only for connected graph  
 • does not contain any cycle  
 •  $N$  vertices, the spanning tree

will have exactly  $N-1$  edges

- Cayley's formula: no. of Spanning tree in a complete graph with  $N$  vertices is  $N^{N-2}$ .
- Complete graph can be obtained by removing  $\frac{N(N+1)}{2}$  edges,  $\Rightarrow$  no. of edges  $\Delta = \frac{N(N+1)}{2}$  of vertices

## # Minimum Spanning Tree (MST)

- It is a tree where the total edge weight  $w_8$  is minimized.
- For graph with weights, it ensures the minimum cost while connecting all vertices

Properties:

- $V$  vertices with  $V-1$  edges
- acyclic (no cycle)
- Not unique, diff. configuration, can have same total  $w_8$ .

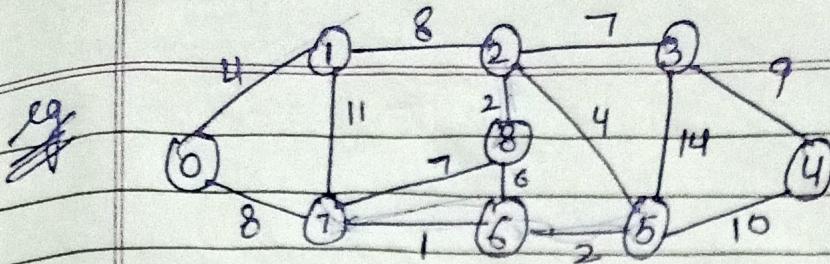

- Cut Property: Minimum weight edge crossing a partition of vertices is always a part of MST.

## # Algo to find MST

1. Kruskal's Algo: Approach: Greedy.

1. Sort edges by  $w_8$
2. Iteratively add the smallest edge, that does not form cycle.
3. Pick smallest edge. If there is cycle  $\rightarrow$  skip it.

~~Applicability~~ of Network design,

|                          | W8 | Source | Destination |
|--------------------------|----|--------|-------------|
| 1                        | 7  | 6      |             |
| 2                        | 8  | 2      |             |
| 2                        | 6  | 5      |             |
